A construction material, provided and renewable by Nature, with predictable performance, taking carbon from the atmosphere and locking it away for decades, with low energy demand and a feel good aesthetic, appreciated by almost everyone – that’s treated wood.

Wood is part of the bioeconomy, can be sourced responsibly, is a flexible and adaptable material that can be used efficiently and aligns with the concept of a circular economy. At the end of its life wood can be reused in a cascading process of uses, recycling or recovery of energy. Wood is consequently a truly renewable construction material.

Wood offers a simple way to reduce the CO₂ emissions that are understood to be the main cause of climate change through:

- the carbon sink effect of the forests;
- the carbon storage effect of wood products;
- substitution for carbon-intensive materials.

Not only is the production and processing of wood highly energy-efficient, giving wood products an ultra-low carbon footprint, but wood can often be used to substitute for materials like steel, aluminium, concrete or plastics, which require large amounts of energy to produce.

Every cubic metre of wood used as a substitute for other building materials reduces CO₂ emissions to the atmosphere by an average of 11 tonnes (t). If this is added to the 0.9 t CO₂ stored in wood, each cubic metre of wood saves a total of 2.0 t CO₂. Based on these figures, a 10% increase in the percentage of houses in Europe whose main structural components are wood, produces sufficient CO₂ savings to account for about 25% of the reductions prescribed by the Kyoto Protocol*.

**SUSTAINABILITY**

Sustainability is most often defined as meeting the needs of the present without compromising the ability of future generations to meet theirs**.

For true sustainability, we need to integrate the goals of a high quality of life, health and prosperity with social justice and maintaining the earth’s capacity to support life in all its diversity. These social, economic and environmental goals are interdependent and mutually reinforcing and are recognised widely as the three aspects of sustainability: economic, environmental and social.

*International Institute for Environment and Development, Using Wood Products to Mitigate Climate Change, 2004

**BS ISO 20400:2017 Sustainable procurement - Guidance
Only through balancing social, environmental and economic aspects can we achieve true sustainability. Both treated wood and the biocides used in wood protection conform to the principles of sustainability and for clarity these are addressed separately.

“These social, economic and environmental goals are interdependent and mutually reinforcing and are recognised widely as the three aspects of sustainability: economic, environmental and social.”

SUSTAINABLE USE OF BIOCIDES

Products containing biocides, such as wood preservatives, are a family of products intended to destroy or control harmful or unwanted organisms (such as fungi and insects) that have detrimental effects on the environment, on animals, on humans, their activities or the products they use or produce. Biocidal products are used in a wide variety of ways by both industrial and professional users as well as by the public.

Sustainable use can be defined for biocidal products as the objective of reducing the risks and impacts of the use of biocidal products on human health, animal health and the environment.

Treated Wood – A Sustainable Choice shows how economic, environmental and social aspects of use of biocides in wood protection deliver sustainability. Wood preservatives were among the first biocidal products to be subject to regulation and standardisation in respect of these characteristics and consequently are now accepted as both safe and effective.

TREATED WOOD AS A SUSTAINABLE MATERIAL

Treated wood is the material of choice in every situation where its characteristics make it suitable. With such protection, designers have the choice of the foremost renewable and sustainable material.

When structures come to the end of their life, treated wood may be segregated for cascading and recycling to extend the useful life of the material. Even when disposal eventually becomes the only option, energy generation by burning returns carbon to the atmosphere where it is turned back into wood by trees using the energy of sunlight. As the amount of CO₂ emitted from combustion is no more than the amount previously stored, burning wood is carbon neutral - a truly circular economy.

Treated Wood – A Sustainable Choice

The full brochure uses four typical use-scenarios to demonstrate the sustainability characteristics of treated wood - wood for construction, railway sleepers, poles for electricity and telecommunications and landscaping and decking. It also sets out the Circular Economy credentials of treated wood and highlights the importance of best practice and education of designers, specifiers, installers and users and how the treated wood industry leads in developing guidance and programmes to assist these groups in optimising sustainable use of treated wood.

The complete brochure - Treated Wood – A Sustainable Choice is available to download from www.wei-ieo.eu or www.ewpm.org.
